

REALISTIC CLIFFS AND ROCKS

— A SHORT (YET DETAILED) GUIDE TO MATERIAL KEY FEATURES —

Material peculiarities:

- It's a layered material
- Highly customizable
- Utilizes an advanced texture packing method for the most optimization

CRUTIAL STEP:

FOR THE CUSTOM SHADER TO WORK CORRECTLY, DON'T FORGET TO INCREASE THE SHADER VARIANT LIMIT IN THE SETTINGS AND PREFERENCES TO A MINIMUM OF 1024

BIG DETAILS

a layer for large details on a rock that are visible from a far distance

1. **Switches textures on and off**, but you still have control over the solid color and smoothness strength.

2. **Automatically increases the tiling** of the texture(s) along the rock scale.

Adjust the BcSm and/or N tiling, when the repetitiveness becomes too obvious or, on the contrary, lacking.

3. Switch between Color and Texture usage. When enabled, change the color with the **Color/Tint** property.

4. **Cavity is bound to the Normal map**. Change its tiling to affect the Cavities' tiling.

SMALL DETAILS

micro details that give that extra oomph in close distances

MOSS LAYER

5. Add a slight color variation, if moss appears too uniform, by blending a unique rock color into it (unique BC texture)

6. **Slope Mask** adds and keeps the moss on top, no matter how you rotate the rock.

7. You can also add the moss to the **cavities** with a slight growth effect.

8. Furthermore, you can **manually add or remove the moss** using Vertex Paint. Choose the vertex color channel you'd like to paint on and toggle the 3rd property to change the paint mode: add or erase the sand.

The Slope and Cavity properties are **cumulative**, meaning you can add moss to both slopes and cavities.

You can change the moss textures in the SSG_Moss sub-graph.

Cavities — Spread property

SNOW LAYER

The properties are identical to those in the Moss Layer, with only one difference - Slope and Cavity are **subtractive**: enabling both ensures the snow appears exclusively within the cavities of upward-facing surfaces.

You can change the snow textures in the SSG_Snow sub-graph.

Mask by Slope

Mask by Slope and Cavities

UNIQUE LAYER

a place for unique textures baked for each rock

R - Cavity Mask
G - Smoothness
B - Ambient Occlusion
 (also used in the snowlayer)

10

Breaks tiling for Big detail layer

FINAL TINT

10. Another way to break the obvious repetitiveness is to enable the **Break Tiling** property, which utilizes a noise texture, and adjust its tiling (frequency) if needed.

TEXTURE HUB

replace the textures with your own to achieve a unique look

Make sure your textures are packed correctly:

BCS

- Base Color (RGB)
- Smoothness (A)

NCAO

- Normal Map (RG)
- Cavity (B)
- Ambient Occlusion (A)
 - **Texture Type:** default
 - **sRGB:** off

RENDER PIPELINE SETUP

By default, Built-In RP light and Post Processing are used.
If you use URP or HDRP, find a corresponding .unitypackage in the corresponding map folder (Overview or Sample map)

By importing the corresponding package,
Light, PPV and MainCamera
in the scene will be overwritten with the settings of the given render pipeline.

In rare cases the scene still may not look as intended, then proceed to a quick troubleshoot:

1. Save and re-open the scene again.

if it didn't work

1. Save and re-open the scene again.
2. Check the lighting settings, if the necessary asset is absent, added from the corresponding folder (for example, Map_Overview -> "Built-in" folder)

3. Save and re-open the scene again.

or

1. Remove the Light, PPV and MainCamera prefabs from the Hierarchy and add them again from the Asset Browser. They are located in the same folder with the RP subpackages./

“That's all Folks!”
